

1,000 connectors. You need six.

Power Automate ships with more than a thousand connectors and 12,000+ actions. Almost everything an office week actually needs runs on six of them.

Outlook

Excel

SharePoint

+ Teams, Forms, Approvals →

01

CONNECTOR 01 — OUTLOOK

The inbox is a trigger.

Mail arriving is the most useful starting gun in the product. One message can open a row in a spreadsheet, drop a file into SharePoint, or ping a channel — without anyone opening the inbox.

Reads	Sender, subject, body, date, attachments
--------------	--

Writes	Sends mail as you, on a schedule or a rule
---------------	--

Pairs with	Excel and SharePoint, almost always
-------------------	-------------------------------------

02

CONNECTOR 02 — EXCEL

A table is a database.

Format a range as a table and Power Automate can read it, add to it and update it row by row. No server, no schema meeting — the spreadsheet people already keep becomes the thing the flow reads from and writes to.

Reads	Every row, as a list you can loop over
--------------	--

Writes	New rows, and updates to the ones there
---------------	---

Catch	It must be a real table, not just cells
--------------	---

03

CONNECTOR 03 — SHAREPOINT

Where files go to be found.

A document library is a folder with a memory — versions, permissions and metadata, all searchable. Once a file lands there it stops being an attachment somebody has to go hunting for.

Reads

Files, folders and list items

Writes

Creates files, updates rows in a list

Catch

Decide the folder path before you build

04

CONNECTOR 04 — TEAMS

Where people actually look.

An email competes with two hundred others. A message in a channel sits beside the work it refers to, and everyone who needs it reads the same thread instead of five separate forwards.

Reads

Messages, mentions, channel activity

Writes

Posts messages and adaptive cards

Catch

A channel keeps the record. A DM does not.

05

CONNECTOR 05 — FORMS

The front door for information.

Forms is how facts get in without going through a mailbox. Four fields and a submit button, and the answer arrives already structured — labelled, typed, and ready to file somewhere useful.

Reads

Every response, field by field

Writes

Nothing — collecting is the whole job

Catch

Fetch the details — the trigger only gives an id

06

CONNECTOR 06 — APPROVALS

A decision, with a paper trail.

Approvals is built into Power Automate itself — no extra licence, no separate tool. It sends the request, waits as long as it takes, and records the outcome against a name and a timestamp.

Reads

Approve or reject, plus the comment

Writes

Who decided what, and when they did

Catch

Decide what happens when nobody answers

Six connectors. Endless pairs.

None of these is impressive alone. The value shows up the moment two of them are wired together and a job that used to need a person stops needing one.

The log writes itself

Attachments file themselves

Answers land where the work is

Which pair would you wire up first? I read every reply.
